Ring theory

## Definition

$(G, *, e)$  is a group if for all  $a, b, c \in G$ ,

$$\textcircled{1} \quad a * (b * c) = (a * b) * c,$$

$$\textcircled{2} \quad a * e = e * a = a,$$

$$\textcircled{3} \quad \text{exists unique } a^{-1} \in G \text{ such that } a * a^{-1} = a^{-1} * a = 1.$$

If  $a * b = b * a$  always, then abelian group.

## Lemma

*If  $R$  commutative unitary ring, then  $R^* = \{r \in R \mid r \text{ is a unit}\}$  is an abelian group under multiplication. In particular, if  $R$  field, then  $R^* = R \setminus \{0\}$ .*

Remember: in  $\mathbb{Z}_n$ ,  $g = [a]_n$  invertible iff  $\gcd(a, n) = 1$ .

## Definition

$\mathbb{Z} \ni n > 1$ .

- $\mathbb{Z}_n^* = \{ [a]_n \mid \gcd(a, n) = 1 \}$ .
- $\phi(n) = |\{ 1 \leq a < n \mid \gcd(a, n) = 1 \}| = |\mathbb{Z}_n^*|$ .

## Example

$\mathbb{Z}_5^* = \{ [1]_5, [2]_5, [3]_5, [4]_5 \}$ ,  $\mathbb{Z}_6^* = \{ [1]_6, [5]_6 \}$ .

## Example

Multiplication in  $\mathbb{Z}_5^*$  and  $\mathbb{Z}_8^*$

*	1	2	3	4
1	1	2	3	4
2	2	4	1	3
3	3	1	4	2
4	4	3	2	1

*	1	3	5	7
1	1	3	5	7
3	3	1	7	5
5	5	7	1	3
7	7	5	3	1

## Definition

- $G$  finite group,  $g \in G$ .
- $g^2 = g * g$ ,  $g^3 = g * g * g$ , et cetera.
- $g^{-2} = g^{-1} * g^{-1} = (g * g)^{-1}$ .
- $g^i * g^j = g^{i+j}$ .
- $g \in G$  has order  $o(g) = n$  if  $g^n = 1$  but  $g^m \neq 1$  for  $1 \leq m < n$ .
- Exists since  $g^i = g^j$  implies  $g^{i-j} = g^0 = 1$ .
- $g^s = 1$  iff  $n|s$ .
- $g^i = g^j$  iff  $i \equiv j \pmod n$ .
- Say that  $a$  has (multiplicative) order  $n$  modulo  $m$  if  $o([a]_m) = n$ , i.e. if  $a^n \equiv 1 \pmod m$  but not for smaller power.

## Example

- $3^2 = 9 \equiv 1 \pmod{8}$ , so 3 has multiplicative order 2 modulo 8.
- $3^2 = 9 \equiv 4 \pmod{5}$ ,  $3^3 = 27 \equiv 2 \pmod{5}$ ,  $3^4 = 81 \equiv 1 \pmod{5}$ , so 3 has multiplicative order 4 modulo 5.

## Definition

- $G$  group,  $*$  operation, 1 unit
- $g \in G$
- $\langle g \rangle = \{g^n \mid n \in \mathbb{Z}\}$
- Subgroup of  $G$ , smallest that contain  $g$
- Cyclic subgroup **generated by  $g$**
- If  $G = \langle g \rangle$  then  $G$  cyclic group,  $g$  generator
- Additively:  $(G, +, 0)$ ,  
 $\langle g \rangle = \{ng \mid n \in \mathbb{Z}\}$

## Lemma

- $o(g) = |\langle g \rangle|$
- $(\mathbb{Z}_n, +, [0]_n) = \langle [1]_n \rangle$
- $\mathbb{Z} = \langle 1 \rangle$
- $\mathbb{Z}_5^* = \langle [2]_5 \rangle$
- $\mathbb{Z}_8^*$  *not cyclic*

Direct products of  
groups

Fermat, Euler

Euler's thm

Fermat

Calculating  $a^b$   
mod  $n$

Ring theory

- $G, H$  groups
- $f : G \rightarrow H$  bijection,  
 $f(g_1 * g_2) = f(g_1) * f(g_2)$
- $G \simeq H$ ,  $G$  and  $H$  **isomorphic**
- Same structure, different name for elements
- All properties preserved
- In particular, up to iso, only one cyclic of size  $n$ , call it  $C_n$ .
- $(\mathbb{Z}_n, +) \simeq C_n$
- $(\mathbb{Z}, +) \simeq C_\infty$ ,
- $(\mathbb{Z}_5^*, *) \simeq C_4$

## Definition

- $G, H$  groups
- $G \times H = \{(g, h) \mid g \in G, h \in H\}$
- Componentwise addition and multiplication

## Lemma

- ①  $G, H$  groups
- ②  $g \in G, h \in H$ , finite orders
- ③  $(g, h) \in G \times H$
- ④ Then  $o((g, h)) = \text{lcm}(o(r), o(s))$

## Theorem

$$C_{mn} \simeq C_m \times C_n \text{ iff } \gcd(m, n) = 1$$

## Example

- $C_3 \times C_5 \simeq C_{15}$
- $([4]_3, [4]_5) \longleftrightarrow [4]_{15}$

## Theorem (Lagrange)

- $G$  group
- $|G| = n < \infty$
- $g \in G$
- Then  $o(g) | n$

## Proof.

Not hard at all, but needs some machinery (cosets). □

We will prove this for the important special case  $G = \mathbb{Z}_n^*$ , using elementary methods.

## Theorem (Euler)

If  $\gcd(a, n) = 1$  then

$$a^{\phi(n)} \equiv 1 \pmod{n} \quad (*)$$

Equivalently,  $[a]_n^{\phi(n)} = [1]_n \in \mathbb{Z}_n^*$ .

## Proof.

Put  $s = \phi(n)$ . Let  $T = \{t_1, \dots, t_s\}$  be a choice of one elem from each class in  $\mathbb{Z}_n^*$ .

Claim:  $aT$  also one from each. All  $at_i$  non-congruent modulo  $n$ , as before. Since  $\gcd(t_i, n) = 1$  and  $\gcd(a, n) = 1$  then  $\gcd(at_i, n) = 1$ .

$$1 * (t_1 t_2 \cdots t_s) \equiv (at_1)(at_2) \cdots (at_s) \equiv a^s (t_1 t_2 \cdots t_s) \pmod{n}$$

Cancel  $t_1 t_2 \cdots t_s$ , you are allowed!

## Example

- $n = 8, T = \{1, 3, 5, 7\},$
- $a = 5, aT = \{5, 15, 25, 35\} \equiv \{5, 7, 1, 3\} \pmod{8},$
- $5t_1 * 5t_2 * 5t_3 * 5t_4 \equiv 5 * 7 * 1 * 3 \equiv 1 * 3 * 7 * 5 \equiv 1 \pmod{8}$
- $5t_1 * 5t_2 * 5t_3 * 5t_4 \equiv 5^4 * t_1 t_2 t_3 t_4 \equiv 5^4 * 1 * 3 * 5 * 7 \equiv 1 * 1 \pmod{8}$
- $n = 3, T = \{1, 2\},$
- $a = 2, aT = \{2, 4\} \equiv \{2, 1\} \pmod{3},$
- $2t_1 * 2t_2 \equiv 2 * 1 \equiv 1 * 2 \equiv 2 \pmod{3}$
- $2t_1 * 2t_2 \equiv 2^2 * t_1 * t_2 \equiv 2^2 * 1 * 2 \equiv 2^2 * 2 \pmod{3}$

## Theorem (Fermat)

Suppose  $p$  prime,  $p \nmid a$ . Then

$$a^{p-1} \equiv 1 \pmod{p} \quad (**)$$

Equivalently,  $[a]_p^{p-1} = [1]_p \in \mathbb{Z}_p^*$ .

## Proof.

$$\phi(p) = p - 1.$$

## Example

What is the remainder when dividing  $1247^{1231}$  with 7?

$$\begin{aligned}1248^{1231} &\equiv (178 * 7 + 2)^{205*6+1} \pmod{7} \\ &\equiv 2^{205*6+1} \pmod{7} \\ &\equiv 2^{205*6} * 2^1 \pmod{7} \\ &\equiv (2^6)^{205} * 2^1 \pmod{7} \\ &\equiv 1^{205} * 2^1 \pmod{7} \\ &\equiv 2 \pmod{7}\end{aligned}$$

## Example (Repeated squaring)

What is  $3^{19}$  modulo 23?

$$3^0 \equiv 1 \pmod{23}$$

$$3^1 \equiv 3 \pmod{23}$$

$$3^2 \equiv 3^2 \equiv 9 \pmod{23}$$

$$3^4 \equiv (3^2)^2 \equiv 81 \equiv 12 \pmod{23}$$

$$3^8 \equiv (3^4)^2 \equiv 12^2 \equiv 6 \pmod{23}$$

$$3^{16} \equiv (3^8)^2 \equiv 6^2 \equiv 13 \pmod{23}$$

so

$$3^{19} = 3^{16+2+1} = 3^{16} * 3^2 * 3^1 \equiv 13 * 9 * 3 \equiv 6 \pmod{23}$$

## Example (Fermat)

What is  $3^{19}$  modulo 17?

$$3^{19} = 3^{16+3} = 3^{16} * 3^3 \equiv 3^3 \equiv 10 \pmod{17}$$

## Example (CRT)

What is  $x = 3^{19}$  modulo  $17 * 23 = 391$ ?

$$x \equiv 10 \pmod{17}$$

$$x \equiv 6 \pmod{23}$$

so

$$x \equiv 230 \pmod{391}$$

## Definition

- $R, S$  commutative, unitary rings
- $T = R \times S = \{ (r, s) \mid r \in R, s \in S \}$
- Componentwise addition and multiplication
- $R \simeq S$  iff exists bijection  $F : R \rightarrow S$  which preserves multiplication and addition:
  - ①  $F(a + b) = F(a) + F(b)$
  - ②  $F(ab) = F(a)F(b)$

## Theorem

- 1  $R, S$  commutative, unitary rings
- 2  $T = R \times S$
- 3 Then  $T^* \simeq R^* \times S^*$

## Theorem

- $\mathbb{Z}_{mn} \simeq \mathbb{Z}_m \times \mathbb{Z}_n$  iff  $\gcd(m, n) = 1$
- If  $\gcd(m, n) = 1$  then  $\mathbb{Z}_{mn}^* \simeq \mathbb{Z}_m^* \times \mathbb{Z}_n^*$

## Example

- $m = 3, n = 4$
- $\gcd(m, n) = 1$
- $\mathbb{Z}_3 \times \mathbb{Z}_4 \simeq \mathbb{Z}_{12}$  as rings
- $\mathbb{Z}_3^* \simeq C_2, \mathbb{Z}_4^* \simeq C_2$
- $\mathbb{Z}_{12}^* \simeq C_2 \times C_2 \not\simeq C_4$
- Multiplication tables:

$$\mathbb{Z}_3^*$$

*	1	2
1	1	2
2	2	1

$$\mathbb{Z}_4^*$$

*	1	3
1	1	3
3	3	1

$$\mathbb{Z}_{12}^*$$

*	1	5	7	11
1	1	5	7	11
5	5	1	11	7
7	7	11	1	5
11	11	7	5	1
